Lab: 1 Working with markup

To see markup in action, point your browser to

https://htmledit.squarefree.com/,

where you can write some hypertext markup and see how it looks on your browser. The blue box at the top holds the markup, and it can be edited by you! The box below shows how the browser renders the markup. Do the following exercises on the squarefree webpage and answer the questions.

- 1. Insert before the word magically and insert after the word magically. What did this accomplish? Note: em is short for emphasis!
- 2. Copy and paste the following code into the webpage.

```
A list of some common HTML markup

    <tt>p</tt> is short for <b>p</b>aragraph
    <tt>a</tt> is short for <b>a</b>nchor (which can indicate a link or a place to link to)
    <tt>ol</tt> is short for <b>o</b>rdered <b>l</b>ist
    <tt>li><tt>li><tt>li><tt>li><tt>li><tt>li><tt>li></tt>
```

Notice that markup can be nested -- the b and /b tags above are inside the li and /li tags, which are between the ol and /ol tags.

- 3. What happens to text between the and tags?
- 4. What happens to text between the <tt> and </tt> tags?
- 5. Now change the and tags to and tags. What happens to the displayed page (in the white box)? Note: ul is short for unordered list.

Make a new ordered list and use it to store your answers to the lab questions #1, #2, etc.

- 6. Notice how the b and /b tags in the last sentence of the copy/pasted code above are missing the usual angle brackets. What happens if you put them in?
- 7. This is a problem in all markup languages some characters have special meaning. In HTML there are so-called <u>escape characters</u> to work around this issue. Google the phrase "html escape characters" and see if you can re-write the last sentence so that things **look like** a tag, but don't **act like** a tag!
- 8. Look up how to use the ... and tags to make a link to another website and embed an image in your page.
- 9. Try writing some text and put a single **
>** tag somewhere. What happens? Why doesn't it need a "closing" tag?
- 10. Similarly, what does the <hr> tag do?
- 11. There are lots of different computer programs ("browsers") that need to translate the html source code of the webpages you visit into the beautiful layouts you see on your screen. How many different browsers can you think of?
- 12. Who is in charge of deciding what those browsers need to recognize as official html code? (Hint: search the internet for "W3C.") Who is in charge of that organization, and where do its profits go?
